

16 audited benchmark-arms; on the 14 where both units are defined, 5 patient-level intervals reach chance and 9 do not

- patient-level interval reaches chance or lies below it
- drop from the line of agreement
- patient-level interval lies wholly above chance
- slice AUC = patient AUC
- still pooled out of fold (constant predictor $\neq 0.500$)
- only one unit is defined (plotted in a gutter)

PI-CAI, case level: no slice index in that label file, so no slice-level reading exists; the value shown is its secondary model, two of whose four inputs are clinical.
 Duke Breast: patient-level AUC is undefined because all 922 of its 922 patients are positive; this arm is also still pooled out of fold.
 All eight DeepLesion body-part arms are plotted; the label there is the anatomic region, so no divergence is expected.
