

15 audited benchmark-arms; on the 13 where both units are defined, 4 patient-level intervals reach chance and 9 do not

- patient-level interval reaches chance or lies below it
- slice AUC = patient AUC
- drop from the line of agreement
- only one unit is defined (plotted in a gutter)
- patient-level interval lies wholly above chance

PI-CAI, case level: no slice index in that label file, so no slice-level reading exists; the value shown is its secondary model, two of whose four inputs are clinical.

Duke Breast: patient-level AUC is undefined because all 922 of its 922 patients are positive.

All eight DeepLesion body-part arms are plotted; the label there is the anatomic region, so no divergence is expected.

Every arm plotted is scored by a single fit on a subject-disjoint split; the constant predictor is exactly 0.500 on all of them.
